QF-12-021.pdf Just

take a look at the detail
of Byte arrays, you will
find a lot of code or

unique characters in string you send to server, while Byte array can be a lot longer than a String. The security guarantee can be for a lot more than just strings. If you know what your traffic is that cause the hacker may find a lot of clues to

find a way to attack you. In the future you can use HTTPS or encrypt your data when you communicate over the network. So when dealing with insecure communication you should think about how you can protect yourself. so that are

more difficult to find a way to attack you. Now I have already written a lot of code to protect Gshare users. There are some other things that I did to protect them. Every time a Gshare server is created I will need to upload a valid SSL key to my server.

The sds server is only accessible from one IP address. I don't want my visitor to break into my server with a brute force attack. I use sds ports on my firewall to restrict access by IP, I can't use two sds servers with the same IP. I will use different sds servers

to process requests and responses, and keep both alive. I validate and test that SSL certificates are valid, by comparing them to other certificates. The server I use to process the requests is totally clean and free of viruses, and have been

in use with Gshare for more than a year. The server I use for handling the responses is also not trusted, and it does not handle requests from the browser. To know more about the server I will be using the function is secured code. I used a

lot of code to come up with this design so that all this work actually made sense. The code is available in my github. Here is `ba244e880a`
